Shopify speed checklist: 15 fixes, in order

Fix speed before you buy more traffic. In a Deloitte and Google study of 37 brands, a 0.1-second improvement in mobile site speed lifted retail conversions by 8.4%.

> Shopify reports that almost 80% of Shopify stores pass all Core Web Vitals thresholds. If yours does not, the cause is usually apps and scripts added over time, not the platform.

1. Measure first

- [ ] Run pagespeed.web.dev on mobile for your home page, one collection page and your best-selling product page
- [ ] Write down the score and the Largest Contentful Paint (LCP) time for each
- [ ] Re-test after every change below, so you know which change helped

2. Apps and scripts (usually the biggest win)

- [ ] List every installed app and uninstall the ones you no longer use
- [ ] After uninstalling, check your theme code for leftover app snippets that still load
- [ ] Load chat widgets, pop-ups and survey tools after the shopper interacts, not on page load
- [ ] Check that each tracking pixel is installed once; duplicates slow the page and double-count sales

3. Images and media

- [ ] Compress large images before upload; product images rarely need to be wider than 2048 px
- [ ] Lazy-load images below the fold
- [ ] Avoid an autoplay video as the first thing on mobile; use a still image with a play button

4. Theme

- [ ] Use an up-to-date Online Store 2.0 theme and apply its updates
- [ ] Limit custom fonts to two families and the weights you actually use
- [ ] Avoid sliders and carousels at the top of the page on mobile

5. Keep it fast

- [ ] Check Core Web Vitals in Google Search Console once a month
- [ ] Test speed before and after installing any new app
